# 程序代写代做 CS编程辅导

## Q1 - Python to MIPS translation

func:

```
# save the $fp and $ra
addi $sp, $sp, -8 # reserve space for the two registers
sw $ra, 4($sp) # save $ra
sw $fp, 0($sp) # save $fp

addi $fp, $sp, 0 # compute new frame pointer
addi $sp, $sp, -4 # reserve space for result
```

```
# if n <= 0
lw $t0, 8($fp) # load argument n
slt $t0, $0, $t0 # if 0 < n then $t0 = 1
bne $t0, $0, else # if $t0 = 1 (i.e., n > 0) go to else
sw $0, -4($fp) # result = 0
```

```
j endif # jump over else branch
```

else:

```
# compute n-1 and store it in $t0
lw $t0, 8($fp)
addi $t0, $t0, -1
```

```
# save the argument (n-1) in the stack
addi $sp, $sp, -4
sw $t0, 0($sp)
```

```
jal func # call func with n-1 as argument
```

```
addi $sp, $sp, 4 # remove argument
```

```
# result = 4*n + func(n-1)
lw $t0, 8($fp) # load n into $t0
sll $t0, $t0, 2 # 4*n shifting by 2
addi $t0, $t0, $v0, # 4*n + func(n-1)
sw $t0, -4($fp) # store it in result
```

endif:

```
lw $v0, -4($fp) # put result in $v0
```

```
addi $sp, $sp, 4 # remove local
```

```
lw $fp, 0($sp) # restore $fp and $ra
lw $ra, 4($sp)
addi $sp, $sp, 8
```

```
jr $ra # go back to the callee
```

Part 1.f

程序代写代做 CS编程辅导

The iterative version will require exactly the same number of bytes ( $N$ ) as the recursive version, since the number of dynamic objects created during their executions (which are the only ones stored by the program) will not change.

For the MIPS code, nothing is created in the Heap.

Note that, in practice, the program will create objects for integers and will indeed use the Heap.

Part 1.h

The Stack for the iterative version of `func(n)` will contain the argument `n` (4 bytes), the saved `$ra` and `$fp` (4+4 bytes), and the local variable `result` (4 bytes). This means a total of  $N = 16$  bytes for the iterative version.

WeChat: cstutorcs

In the recursive version, the callee will call `func(n)` which will then call itself  $n$  times. And each time it will take  $N$  (16 as we shown above) bytes. That means a total of  $(n+1)*N$  bytes.

## Q3 - CS saves the world

Write the output of the function `mystery` for the input values:

1  
1  
2  
3  
1  
4

What does the function `mystery` compute?

It computes the sum of the digits of  $x$  in base 2.

What is the time complexity of `mystery`, using the  $O()$  notation? Prove your answer.

$O(\log x)$ .

Write the output of the function `enigma` for the input ...

1  
1  
3  
6  
1  
5

What does the function `enigma` compute?

It computes  $\text{mystery}(x) + \text{mystery}(\text{mystery}(x)) + \dots$

What is the time complexity of `enigma`, using the  $O()$  ...

The output of `mystery(x)` has size  $\log(x)$ .

Since `enigma` computes  $\text{mystery}(x) + \text{mystery}(\text{mystery}(x)) + \dots$ , it requires  $T(x) = \log(x) + \log(\log(x)) + \dots$  operations.

Since  $\log(x) \leq x/2$ , we have  $\log(\log(x)) \leq \log(x/2) \leq x/4$ .

Hence  $T(x) \leq x/2 + x/4 + \dots = x$ .

Computing `enigma(x)` is thus in  $O(x)$ .

# 程序代写代做 CS编程辅导

What does `enigma(4095)` return? Justify your answer.

Observe that  $4095 = 2^{11} + 2^{10} + \dots + 2^0$ , hence `mystery(4095)` returns 12.

Therefore `enigma(4095)` returns `enigma(12)`.

`mystery(12)` returns 1.

Hence `enigma(4095)` returns 1.

### Q4 - Natural merging

Write a function which, given a list as input, returns the list of indices between which the input list is already sorted.

```
def find_intervals(l):  
    separators = []  
    for i in range(1, len(l)):  
        if l[i-1] > l[i]:  
            separators.append(i)  
    separators.append(len(l))  
    return separators
```

WeChat: cstutorcs

Assignment Project Exam Help

What is the worst-case time complexity of the ...

It should be  $O(n)$ , where  $n$  is the length of the list. (Direct analysis from code above.)

Email: [tutorcs@163.com](mailto:tutorcs@163.com)

Write a function `natural_merge` which takes the list to ...

QQ: 749389476

```
def natural_merge(l):  
    separators = findintervals(l)  
    while len(separators) > 2:  
        merge(l, separators[0], separators[1], separators[2])  
        separators.pop(1)
```

<https://tutorcs.com>

In the function above it is important not to call `find_intervals` multiple times.

What is the worst-case time complexity of the merge function we have provided?

$O(\text{end-start})$ , i.e. the sum of the length of the two sublists. This is visible in the range used in the two for loops.

What is the best-case time complexity of the algorithm `natural_merge`?

In the best case, the input list is already sorted, and there are only 2 items in the separators list, which means that the only work to do was to call `find_intervals`. Complexity  $O(n)$ , where  $n$  is the length of the input list.

## 程序代写代做 CS编程辅导

What is the worst-case time complexity of the algorithm...

The worst-case occurs when the sublists are merged in the opposite order. In this case, all sublists have size 1, and we merge everything iteratively. There are  $O(n)$  merges to do, the first one with 2 elements, then 3, then 4, 5, ...,  $n$ . Since the merge function has complexity  $O(n)$ , the total time is  $1+2+3+4+\dots+n = O(n^2)$ .

How could a sort with better time complexity be designed using the ideas presented in this question?

Even though we use merging operations, we may end up doing many inefficient "mergings" if the two lists being merged are not balanced in size. Instead of merging from left to right, we could merge smaller lists first.
